RE: New Patent Application Entitled:
IMPROVED GOLF CLUB FACE FLEXURE CONTROL SYSTEM
(CIP of U.S. Serial No. 09/344,172;
Filed 6-24-99)

Dear Sir:

Enclosed herewith is a new Continuation-in-Part patent application in the above case including specification, 12 sheets of drawings (6 sheets formal, 6 sheets informal), a CIP Oath, two Small Entity Declarations, Assignment with attached Cover Sheet, and a return postcard.

My check in the amount of \$541 is enclosed representing \$345 for the basic filing fee, \$156 for four independent claims in excess of three, and \$40 for recording the Assignment.

Please give this application the earliest possible filing date.

Very truly yours,

Dillis V. Allen

CERTIFICATE OF MAILING BY EXPRESS MAIL

This is to certify that the above documents are being deposited with the United States Post Office as Express Mail on July 12, 2000, Express Mail No. TB008569473 US.

Diane K. Mauter

Diane K. Mauter

1. The first step is to identify the key components of the system. This includes understanding the hardware, software, and data involved.

2. Next, we need to define the goals and objectives of the project. This will help us determine what we are trying to achieve and how we will measure success.

3. Once the goals are defined, we can begin to design the system. This involves creating a detailed plan that outlines the architecture, components, and data flow.

4. After the design is complete, we can start implementing the system. This involves writing code, configuring hardware, and testing the system to ensure it meets the requirements.

5. Finally, we need to deploy the system and monitor its performance. This involves installing the system on the target environment and tracking its usage and performance over time.

IMPROVED GOLF CLUB FACE FLEXURE CONTROL SYSTEM

ABSTRACT OF THE DISCLOSURE

An improved line of golf clubs tailored to the swing speed of the golfer. The basic principles of the present invention can be applied to a single club, but optimally these principles are applied to a plurality of different club heads designed to the specific speed range of the golfer; namely, 50 to 65 mph, 66 to 80 mph, 81 to 95 mph, 96 to 105 mph, and 106 to 140 mph. Maximum ball exit speed from the club head is achieved from club face deflection in each of these ranges near the maximum at which the face wall reaches its permanent elastic deformation. To achieve these principles, the face wall firstly is designed so that the face wall modulus of elasticity increases from a low modulus for the low swing speed range to progressively higher modula for the higher swing speed ranges. Face modulus can be altered by a variety of a techniques including face wall thinning, material selection and heat treatment or a combination thereof. In each of the swing speed range clubs, the face has a first modulus of elasticity determined by the face itself and after the face deflects to a predetermined value, the face modulus is significantly increased by a secondary wall parallel to and closely spaced behind the face wall. The face wall impacts the secondary wall at a swing speed near the top of the swing speed range for that particular club. That is, in the low speed, 50 to

00614407-071200

60 mph club, the face wall will impact the secondary wall over 60 mph. Where exactly that impact occurs depends upon the design criteria of the club head designer.

RELATED APPLICATION

This application is a continuation-in-part of United States patent application entitled "GOLF CLUB FACE FLEXURE CONTROL SYSTEM", U.S. Serial No. 09/344,172, Filed: 6-24-99.

BACKGROUND OF THE INVENTION

The primary objective of the present invention is to design golf clubs for a variety of golfers that optimizes the distance the golfer impels the golf ball. To do this from a physics standpoint, it is necessary to obtain a maximum deflection of the ball striking face, or something approaching that maximum, during the collision with the ball while at the same time maintaining the other parameters of the golf club head within acceptable limits.

This spring-like effect of the ball striking face, which is necessary to achieve maximum distance, has been widely misunderstood in the golf industry, even by many golf club designers. Many golf club designers believe that any deflection of the golf club face during impact with its resulting spring-like effect on the golf ball is a design in violation of the Rules of the USGA. This is a myth because virtually all of the thin walled hollow metal wood clubs

slides back and forth on the rod and impacts the face during ball collision to assist in imparting additional energy to the ball 12. This design is in contravention of the Rules of the USGA because it contains moving parts. It should be noted with respect to the Kim patent, that the present invention contemplates moving parts solely in the sense that the club face deflects and that the USGA has recognized that club face deflection by itself does not constitute a moving part nor is it in contravention of past or present USGA Rules.

In my United States Patent No. 5,873,791, entitled "Oversize Metal Wood with Power Tube", issued February 23, 1999, and in my following Continuation-In-Part application, U.S. Patent No. 5,888,148, entitled "Golf Club Head with Power Shaft and Method of Making", issued March 30, 1999, I describe club head designs in which a power piston is provided to increase the modulus of elasticity of the face wall of the club head throughout the swing speeds in each of the swing speed ranges. The object of the present invention, which is to maximize face deflection, is to reduce the modulus of elasticity in each of the swing speed ranges to achieve maximum face deflection in each of the ranges without causing face failure.

Investment casting techniques innovated in the late 1960s have revolutionized the design, construction and performance of golf club heads up to the present time. Initially only novelty putters and irons were investment cast, and it was only until the early years of the 1980s that investment cast metal woods achieved any degree of commercial

00270 2044560

success. The initial iron club heads that were investment cast in the very late 1960s and early 1970s innovated the cavity backed club heads made possible by investment casting which enabled the molder and tool designer to form rather severe surface changes in the tooling that were not possible in prior manufacturing techniques for irons which were predominantly at that time forgings. The forging technology was expensive because of the repetition of forging impacts and the necessity for progressive tooling that rendered the forging process considerably more expensive than the investment casting process and that distinction is true today although there have been recent techniques in forging technology to increase the severity of surface contours albeit them at considerable expense.

The investment casting process, sometimes known as the lost wax process, permits the casting of complex shapes found beneficial in golf club technology, because the ceramic material of the mold is formed by dipping a wax master impression repeatedly into a ceramic slurry with drying periods in-between and with a silica coating that permits undercutting and abrupt surface changes almost without limitation since the wax is melted from the interior of the ceramic mold after complete hardening.

This process was adopted in the 1980s to manufacture "wooden" club heads and was found particularly successful because the construction of these heads requires interior undercuts and thin walls because of their stainless steel construction. The metal wood club head, in order to conform to commonly acceptable club head weights on the or-

This technique devised by Mr. Raymont was adopted in the late 1980s by many tool designers of investment cast metal woods to increase the strength of the forward face of the metal woods to maintain the requirement for total overall head weight and to redistribute the weight to the relatively thin investment cast perimeter walls permitting these walls to not only have greater structural integrity and provide easier molding and less rejects, but also to enhance the perimeter weighting of these metal woods.

Another problem addressed by the present invention is the achievement of increasing the benefits of perimeter weighting by simply adding weight to the perimeter of the club head itself. This technique, of course, has found considerable success in low impact club heads such as putters, where overall club head weight is in no way critical, and in fact in many low impact clubs that have found considerable commercial success, the club heads weigh many times that of metal wood heads, sometimes three or four times as heavy.

Increased perimeter weighting has been found difficult because of the weight and impact strength requirements in metal woods. An understanding of perimeter weighting must necessarily include a discussion of the parameter radius of gyration. The radius of gyration in a golf club head is defined as the radius from the geometric or ball striking axis of the club along the club face to points of club head mass under consideration. Thus, in effect the radius of gyration is the moment arm or torquing arm for a given mass under consideration about the ball striking point. The total moments acting on the ball during impact

The Chancellor, U.S. Patent No. 3,589,731, shows a movable weight between the back and the front of the club that allegedly corrects hooking and slicing.

The Glover, U.S. Patent No. 3,692,306, shows a weight port integral with the club face in Fig. 6, but Glover's club head is a low modulus resin and is not perimeter weighted.

The Zebelean, U.S. Patent No. 4,214,754, shows support members 32 in Fig. 10, but they are not connected to the face nor are they concentrated behind the sweet spot.

The Yamada, U.S. Patent No. 4,535,990, shows a shaft between the rear of the face wall and a back portion of the club, but the Yamada club head is not a high modulus material, and the patent is silent as to how the reinforcement member 31 is connected into the club head cavity.

The Chen, et al., U.S. Patent No. 4,681,321, shows webs 31 molded inside the club head, but both the club head and the webs are low modulus materials.

The Kobayashi, U.S. Patent No. 4,732,389, shows a brass plate and a rod that engage the rear of the ball striking face, but the patent is silent as to how it is attached to the face and the club head is solid wood and not a perimeter weighted club head.

The Shearer, U.S. Patent No. 4,944,515, shows a shaft 24 either cast or attached inside the club head. The Sheer patent is silent as to how the shaft could be cast in the club head and in the alternative suggests that it be fixed in after the club head is made, the patent is silent as to how it might be fixed inside.

The Shiotani, et al., U.S. Patent No. 4,988,104, shows an insert 15 that is insert molded inside the golf club head, but the club head is a resin type low modulus material, and there is no specific attachment of the insert into the head other than that which results from the insert molding process.

The Duclos, U.S. Patent No. 5,176,383, discloses a low modulus graphite head having a rod formed on the rear of the ball striking face. The low modulus head provides the Duclos club with minimal perimeter weighting.

The Atkins, U.S. Patent No. 5,464,211, shows a plate 30 that is threaded from the rear of the club against the forward face which he refers to as a "jack screw". The plate 30 is epoxied to the rear of the face wall and such a design will fail under the extreme high impact loadings of a 150 ft./sec. impact with a golf ball.

The Rigal, et al., U.S. Patent No. 5,547,427, shows partitions. In the Fig. 9 embodiment, the rod 74 is placed in tension which detracts from rigidifying the front face. In the Fig. 10 embodiment, the rod 23 is not integral with the front face.

A further principle problem addressed in the present invention has resulted from the use of light-weight alloys to produce "jumbo" or oversized metal woods that are particularly popular in today's golfing market. These use light-weight metals such as high titanium alloys that permit the club head to be made larger, providing increased perimeter weighting and an easier to hit larger sweet spot. However, there is a trade-off to this large sweet spot and

0054407-071200

that is a diminution in ball distance travel or in short, the ball does not travel as far as it does with smaller stainless steel heads, which concentrate more mass behind the ball. This in part explains why professionals on the regular tour rarely use very large titanium club heads.

This diminution in ball distance in jumbo titanium alloys, or other light-weight alloy heads, is believed caused by three factors. First, the very large club heads spread the perimeter wall support points from the ball striking area, causing the face to flex more than smaller heads resulting in a badly delayed rebound of the face. If one can imagine a flat horizontal 1" x 6" pine board supported at points two feet apart and a similar board supported at points 10 feet apart, both with a 200 lb. weight in the middle of the boards, the second board will bend substantially more. This oversimplified is what causes in part the greater face flexure in the jumbo metal woods. Secondly, while titanium is a hard material, it has a modulus of elasticity less than half that of ferrous alloys. The lower the modulus, the greater the strain or deflections, for a given load. It should also be noted that today's high titanium alloy jumbo metal wood heads with volumes in the range of 250 to 300 cm.³, have relatively thin wall thicknesses, less than 0.125, and in some cases substantially less than 0.125 inches, which exacerbates the problem of face flexure and slow face rebound.

These three factors all contribute to an incomplete face recovery during ball impact. That is, the club face bends inwardly at ball impact to a state of tension and

then returns at some point in time to its normal relaxed position. The rebound of the club face, or its return to its relaxed position, should ideally assist in propelling the ball from the club face. In these prior high titanium jumbo club heads however, the face wall does not fully recover until after the ball leaves the club face, thereby dissipating as waste a portion of the club head energy.

In my application, U.S. Serial No. 08/859,282, Filed: 5-19-97, now U.S. Patent No. 5,873,791, a high modulus golf club head of the "wood" type is provided with a power shaft, a rod for increasing the resonant frequency and decreasing the rebound time of the face, integral at its forward end with the ball striking wall behind the sweet spot and integral with a rear portion of the club head at its rear end. While others have attempted supports for other purposes such as face reinforcement and club sound or feel, they have not been successful because these clubs are either not possible to manufacture, or will fail under the rigors of a 100 to 150 ft./sec. impact velocity against a golf ball.

In that application a jumbo club head in the range of 250 to 300 cm.³ is disclosed constructed of a hard, light-weight alloy such as titanium or beryllium, with an integral power shaft extending from behind the club face sweet spot to a rear portion of the club head.

The power shaft according to that application was constructed of a metal alloy substantially similar to the metal alloy of the club head so it can be welded or fixed integrally to the sweet spot on the rear of the face wall

and cast, welded or fixed integrally to a rear portion of the club head at its rear end. While welding similar metals is certainly not a new concept, it is difficult to weld, for example, a 0.625 inch diameter shaft with a .035 to .049 inch wall thickness directly to the club head face wall and rear wall because the face wall and rear wall, because of their large areas, require higher heating and welding temperatures resulting in heat distortion of the face wall and rear club head.

To obviate this problem, that application discloses a face wall sweet spot and the rear club head portion with cast in annular retainer walls to which the power shaft is welded. These retainers buff the heat sink effect of the face wall and club head portion and minimize heat distortion in these surfaces during welding.

The power shaft according to that invention is a compromise between club head designs to enhance perimeter weighting and increase the sweet spot area, and the ball distance producing designs that concentrate more mass directly behind the ball at impact.

Hence, I disclose in U.S. Serial No. 08/859,282, a compromise between increased radius of gyration and increased ball distance.

Another important aspect of my U.S. Patent No. 5,888,148, and my U.S. Patent No. 5,873,791, is the customizing of the golf club to the swing speed of the golfer. Golfers swing speed differ radically from about 88 ft/sec. up to as much as 180/ft/sec.(123 mph). The club face at impact becomes concave and before or after the ball leaves the

09544307 074200

face, the face rebounds to its natural shape. The time the ball remains on the face is surprisingly about the same for the slow swings and the fast, but the harder swinger will compress the ball further. Ideally, for both the fast and slow swinger, the face will rebound precisely as the ball is exiting the face to enhance ball exit velocity. But to do this, bearing in mind time of impact, about 5-7 milli/sec., is about the same for all swing speeds, the face must recover at a faster rate for the high speed swing because it has a greater face deflection. To achieve this, the line of woods gives the higher speed swinger a progressively higher face wall resonant frequency than the lower speed swing. Numerous studies have been made analoging the natural or resonant frequencies of bodies to the rebound of the bodies after bending or deformation and those have been adopted here. But it should be noted however, the natural frequency of all linear structures increases with increasing stiffness and decreases with increasing mass.

In a free body system, the natural frequency of the system f is equal to $\frac{1}{2\pi} (K/M)^{1/2}$ where f is in cycle per unit of time, of a beam pinned at both ends and center loaded, as the face of a golf club, the spring constant K ; i.e., force/unit deflection at point of L and is equal to

$$\frac{3 EI}{L^3}$$

when E is the modulus of elasticity of the material, I is the moment of inertia, and L is the unsupported length.

While titanium is a very hard material, it has a relatively low modulus(E) of $16.8 \text{ psi} \times 10^6$ compared to stainless steel, which is $30 \text{ psi} \times 10^6$. And the natural frequency varies as \sqrt{E} when E is the modulus of elasticity.

Hence, it is when equating the rebound of a titanium face to that of steel the titanium face must be stiffened significantly more and in quantified amounts, and the present invention provides the tools to do that.

As noted above while golfer swing speeds differ greatly, time of ball impact does not and total club head weight stays in the range of 195 to 205 grams for most all swing speeds. Thus to achieve face frequency matching to swing speed, my U.S. Patent No. 5,873,791, provided a means to vary face stiffness while maintaining about the same overall head weight.

Toward this end the face wall was stiffened in my U.S. Patent No. 5,873,791, by selecting a power shaft of varying wall thickness, which of course are of different weight, to equate the weights, the rods are provided with transverse weight ports for high density weights, that yield the same overall weight to the club head but varying stiffness and natural frequency to the club face. In this way, faster face rebound is provided for the higher speed golfer and hence slower face rebound for the slower speed golfer to assure that face rebound coincides with ball exit event on the club face.

Using these philosophies, a line of relatively high modulus metal woods was developed, and while stainless steel can be used, the choice is lighter weight alloys

09514407-071200

having a high surface hardness such as a high titanium or a high beryllium alloy. Utilizing a single club head body tool (the club head bodies are the same initially as are their face walls), the system includes a plurality of interchangeable power shafts providing increasing stiffness and resonant frequency to the ball striking wall, beginning with thin walled shaft for the slower swinger and progressing to a heavy wall shaft for maximum stiffness and higher resonant frequency for the higher swing speed club.

In accordance with my U.S. Patent No. 5,888,148, a golf club head with a power shaft is provided with an increased modulus of elasticity by preloading the power shaft, and a method of making a golf club head with and without preload is disclosed wherein the club head is cast or formed in forward and rear pieces along a generally vertical parting line, and the two pieces are assembled in clamshell fashion over the power shaft and thereafter the forward and rear pieces are joined by welding or otherwise bonding while the power tube is held in place. In a high volume club head embodiment, above 250 cm.³, constructed of a low modulus alloy compared to stainless steel, the power shaft has a preload, or static compression, to increase the modulus of elasticity of the head and ball striking face. This preloading technique is expanded in another embodiment into a semi-customized line of golf club woods, where the club head modulus of elasticity increases with the golfer's club head speed by progressively increasing preload in the club head line. The power shaft is press fitted into the rear of the ball striking face to reduce bonding and welding dif-

0054407.071200

difficulties in joining the power shaft to the ball striking face. The modulus of the face wall and the power shaft is enhanced by casting or welding the sole plate of the club head along an axial extent directly to the outer surface of the power shaft thereby increasing its columnar strength. By applying opposite axial clamping forces to the two club head pieces during and after welding or other heat bonding, the power shaft is preloaded into a static compression state. When the forward and rear pieces are joined by welding, the axial force application is maintained for a predetermined time after welding and assures that weld relaxation and wall relaxation will not significantly reduce the power shaft preload.

Toward these ends, the club head assembly, in one embodiment of my U.S. Patent No. 5,888,148, represents a deviation and improvement from the golf club head disclosed and claimed in U.S. Patent No. 5,873,791. In that patent, the difficulties in joining the power shaft to the club head have been significantly reduced by a non-invasive joining method. That is, the power shaft is joined to one or both of the club head forward and rear pieces without requiring entry into the club head cavity with a welding tool or other joining instrument. This is accomplished by the provision of a tapered socket and cooperating tapered projection on the power shaft that when forced together under high pressure, the press-fitted tapers create a joint far superior to other bonding techniques, such as epoxy, and one that eliminates heat distortion and other problems associated with the welding of the power shaft.

09644107.071200

The power shaft may be cast with one of the forward and rear pieces, but preferably it is initially formed separately therefrom. As a manufacturing expedient, it is preferred to form the power shaft as a separate molding or forging because it is difficult to control the power shaft dimensional integrity when cast integrally with either the forward or rear piece.

The sole plate has a concave spheroidal central portion that extends upwardly toward the power shaft. The sole plate has edges that are welded or integrally cast with axial portions of the sides of the power shaft. This design significantly increases the columnar modulus of elasticity of the power shaft without increasing weight because it uses the sole plate as a support, and in effect the power shaft forms a part of the sole plate to further increase the strength of the sole plate itself. This is also a significant weight saving technique. Firstly, because the power shaft forms part of the sole plate, sole plate weight is reduced, and secondly, the power shaft modulus is increased without any increase in weight in the power shaft.

Another aspect of my U.S. Patent No. 5,888,148, is the incorporation of the power shaft preloading technique into an entire line of "wood" type club heads. In this embodiment, variable modulus of elasticity of the club head face wall is achieved, not by providing variable power shaft wall thickness, as in my application, U.S. Serial No. 859,282, but rather by varying the magnitude of the static preload of the power shaft acting on the rear face of the club head ball striking wall. Preload variation is carried

through a semi-customized line of drivers(or fairway woods) including, for example, four differently preloaded drivers. The first driver is designed for the very low swing speed golfer, the fourth for the highest swing speed golfer. With this technique, the first driver has a power shaft preload of about 20 kg., and the fourth has a preload of about 100 kg. The second and third drivers in the line have proportionately intermediate preloads for the intermediate swing speeds.

In short, a high swing speed golfer plays with the highest preload club head, and the lower swing speed golfer plays with a progressively lower preloads depending upon their individual swing speeds.

In my parent application, U.S. Serial No. 09/344,172, Filed: 6-24-99, I disclose a piston that is spaced from the rear of the face wall that impacts the face wall near its maximum deflection point.

It is a primary object of the present invention to reduce face modulus to provide maximum face flexure.

SUMMARY OF THE PRESENT INVENTION

In accordance with the present invention, a line of golf clubs is provided tailored to the swing speed of the golfer.

The present invention includes a secondary wall behind the face wall that significantly raises the ball striking face wall modulus of elasticity somewhere in the speed range of each of the five ranges. By raising the face

wall modulus as the face deflects in each of the ranges, the elastic limit of the face is never exceeded even if the club head is swung at a significantly higher speed than the maximum speed within the range. This significant increase in face wall modulus within the range also increases the energy transferred to the ball and ball exit velocity.

In the specific embodiments disclosed in this application, each club in the line has an increasing face thickness from the low swing speed club to the highest swing speed club. Face modulus can be varied using other techniques including material selection and heat treatment, and others.

An object of the present invention is to maximize the spring effect to club head impacts to the golf ball to maximize energy transfer to the ball and ball distance. To do this, the face wall is thinned to the point of near failure in each of the speed ranges and hardened by heat treatment. Face material is selected to achieve maximum hardness to enhance its spring effect. The beta titanium alloys can achieve high Rockwell or Vickers hardness when properly heat treated, and can be used to achieve the benefits of the present invention, but other alloys of other metals such as steel may be used, as well as other titanium alloys such as 6A14V. One beta titanium alloy that has been found particularly beneficial is Ti-15Mo-5Zr-3Al(Aluminum) ST 735 degrees C, Aged 500 degrees C, a solution treated alloy having a high tensile strength 213 kpsi, a high harness of Vickers 412, a modulus of elasticity of 14,500 ksi, and an elongation to break of 14%.

In each of the four clubs in the line (they may be more or less in the line), a secondary wall is positioned parallel to and just behind the face wall. As the face wall deflects, at a sufficient club head speed, it will impact the secondary wall, thereby raising the effective modulus of the face wall and prevent the face wall from failing.

The four exemplary clubs include a 50-65 mph club, a 66 to 80 mph club, an 81 to 95 mph club, and 96 to 105 mph club. An additional club for over 105 mph speeds is also desirable. This is because a thinner wall will deflect more at its proportional limit than a thicker wall.

In each of the clubs, the secondary wall is designed and positioned to be impacted by the face wall at about 80% of the proportional limit of the face wall. The proportional limit is the force applied to the face wall where permanent deformation occurs. 80% is selected because face failure can occur before the proportional limit as a result of other causes such as cyclical stress failure or fatigue failure. It should be understood that values above and below 80% are within the scope of the present invention.

It should also be understood that the values for face thickness given in this application; namely, 0.050 to .120 inches and the values for secondary wall spacing; i.e., 105 to 0.040 inches are values for one specific alloy with a specific heat treatment.

With alloy selection and heat treatment, these values will vary in practice and are within the scope of this invention. Since thinner faces offer greater opportunity for greater face deflection, face thickness in the

To understand the design philosophy of the present invention, it is helpful to understand exactly how the club head is designed. Firstly, a fairly large number, approximately 20, of club heads are compression tested, each with a different face modulus of elasticity. Each of these faces is deflected to its elastic limit, and the face deflection at that elastic limit is recorded. This testing is done without the secondary wall in position. After these results are tabulated, the face walls are installed in these club heads with the secondary walls spaced from the bottom of the face wall sockets a distance so that the face wall impacts the piston at a force approximately 80% to 85% of the force recorded at the proportional limit for that club head. However, something greater than 85% may also be appropriate after fatigue testing analysis is completed for the particular club head design in question, and such is within the scope of the present invention.

Then the speed ranges are selected for each club by testing with a mechanical club swinging machine. Face impact with the piston face can be determined by the significant change in impact sound as club head speed increases in the test beyond the secondary wall impact speed.

The inherent result of this design process is to have a minimum face thickness in each speed range reducing club head weight so the additional weight of the secondary wall does not result in overweight club heads. Also, because this design reduces face weight, the saved weight can be moved to the perimeter walls for improved perimeter weighting.

002720 2074560

While the impact of the power piston with the front face may impart additional energy to the ball during impact, its primary function is to permit the club face within a substantial portion of each speed range to flex to its maximum value without exceeding the proportional or elastic limit of the face wall. And face failure is a significant problem in the design of metal wood clubs. This applicant has been designing golf clubs using long driving competition, LDA, for many years, and has knowledge that many of the very well known driver clubs fail as often as once a week for these high swing speed players, in excess of 120 mph, and this phenomenon is not known or experienced by the low swing speed player. The philosophy of the present invention is to permit the slow swing speed player, as well as the high swing player, to press the elastic limit of his club face to maximize club head and face wall energy transfer to the ball.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a front view of a club head according to the present invention;

Fig. 32 is a stress strain curve for each of the club heads illustrated in Figs. 27 to 30.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to the drawings, it should be understood that Figs. 1 to 16 relate to the new subject matter in the present application and that Figs. 17 to 32 correspond to Figs. 1 to 16 in parent application, U.S. Serial No. 09/344,172, Filed: 6-24-99.

Referring initially to Figs. 1 to 16, a club head 10 is illustrated according to the present invention that includes a standard body 11 and interchangeable face walls 12. The body 11 may be formed in forward and rear pieces as described in my U.S. Patent No. 5,888,148.

The body 11 includes an upper crown wall 13, a toe wall 14, a heel wall 15, and a sole plate 17. An external portion 19 of the hosel assembly 20 shown in Fig. 4, projects upwardly from the crown wall 11.

The hosel assembly 20 includes an upper portion 21 and a spaced lower portion 22.

The crown wall 13, the toe wall 14, the heel wall 15, and the sole plate 17 together form the perimeter wall that surrounds the ball striking face wall 12.

As seen in Figs. 5 and 11, a secondary wall 26 is positioned rearwardly behind the face wall 12a and is positioned to be impacted when the club head strikes the golf ball with sufficient club head speed as shown in Fig. 6.

The secondary wall 26 has a unit cellular structure 28 cast integrally therewith that supports and rigidifies the secondary wall 26 reducing secondary wall weight. It should be understood that the secondary wall and the unit cellular structure 28, which takes the form of a honeycombing pattern shown in Fig. 4, are cast integrally with the club head body 11, or if the club head body is formed with forward and rear pieces along a parting line generally along the section line 4-4 of Fig. 3, the secondary wall 26 would be cast with the forward portion of the club head body.

An important aspect of the present invention is that the club head body is identical for all clubs in the line, and only the face walls shown in Figs. 7 to 10 change from one club in the line to another.

As seen in Fig. 14, the club head body has a recess 30 that extends entirely around the face wall 12 and receives a flange 32 on the face wall that extends completely around the face wall. The recess 30 includes a mounting surface 33 and a shoulder 34.

Viewing Figs. 7 to 10, it can be seen that there are four face walls depicted in this portion of the specification. Namely, Fig. 7 illustrates the 50 to 65 mph club face; Fig. 8 depicts the 66 to 80 mph club face; Fig. 9, the 81 to 95 mph club face; and Fig. 10, the 96 to 105 mph club face, and the completed club head assemblies corresponding to these four faces are shown in Figs. 12, 14, 15, and 16 respectively.

Viewing Figs. 7 to 10, where value 38 represents face thickness and value 39 represents secondary wall spacing, as they do also in Figs. 8, 9, and 10, as well as Figs. 12, 14, 15 and 16. The configuration of the flanges 32 permits the use of a standardized club head body 11 and the automatic determination of the secondary wall spacing 39. This is achieved by progressively decreasing the height of the lower mounting surface 41 of the flange 41 as the face thickens in the face walls 12a, 12b, 12c, and 12d. In fact, in the 12d face wall, the mounting surface 41 is recessed above the rear wall 42 of the face wall.

Viewing Fig. 12, which is an assembly of face wall 12a into the standard body 11, the total forward club surface includes a perimeter wall portion 44 on the club head body adjacent shoulder 34. Wall 44 is designed so it is flush with the forward surface 45 of the face wall 12a and requires substantially only weld grinding after the face wall is welded into the recess 30.

Face wall 12b illustrated in Fig. 14, because of the flange 41 projection shown in Fig. 8, positions the forward surface 46 of the face wall below surface 44 so that after welding, surface 44 must be ground down flush with surface 46.

Similarly, the forward surfaces of the face walls 12c and 12d illustrated in Figs. 15 and 16, require progressively more grinding of surface or wall 44 after welding.

As can be seen, this enables the use of a standardized body and the automatic simple achievement of accurate secondary wall-face wall spacing during assembly.

The club head 110 illustrated in Figs. 17 to 26 is preferably constructed of a titanium alloy such as 6AV4, which signifies a high titanium alloy of 6% aluminum, 4% vanadium, and the balance pure titanium. The club head 110 has a volume of 280 cm.³, and ball striking face area of 43.25 cm.³. Aspects of the present invention are applicable to "wood" type club heads having total volumes in the range of 150 to over 300 cm.³, as well as face areas in the range of 25 to over 45 cm.³.

09/344,172

The club head 110 illustrated in Figs. 17 to 23 is the subject of parent application, U.S. Serial No. 09/344,172, and is constructed of three pieces that are joined together in assembly; namely, a club head forward portion 111 illustrated in Fig. 25, a club head rear portion 112 illustrated in Fig. 110, and a power shaft 113 shown in Figs. 27 and 31. The power shaft 113 is cast or formed separately from the rear portion, attached to the rear portion by welding or press-fitting it therein.

Viewing Figs. 17 to 26, the club head 110 is seen to generally include a grooved ball striking face wall 115 having an area of about 43.25 cm.³ and a wall thickness as viewed in the plane of Figs. 17 to 30 that progressively decreases in the club line from Fig. 27 to Fig. 30. In this regard, the wall thicknesses throughout the club head 110 are in the range of 2 to 3 mm. except for the face wall 115, which varies in the line. A crowned top wall 117 extends integrally and rearwardly from the upper portion of the face wall 115, and it has a short integral hosel segment 118 projecting upwardly therefrom with a shaft receiving bore 119 therein that extends through spaced hosel segments 120 and 121 illustrated in Fig. 25.

A heel wall 123 is integral with and extends in an arcuate path rearwardly from the right side of the face wall 115 as viewed in Fig. 17. A toe wall 124 is formed integrally with the face wall 115 and extends rearwardly in an arcuate path from the extreme toe end of the face wall 115 and is also integrally formed with the top wall 117, as is the heel wall 123.

leading edge of the face wall of 54 mm., and the forward portion of the sole plate portion 132 is spaced 22 mm. from the face wall leading edge identified by the letter M in Fig. 23.

Viewing Fig. 25, upper hosel segment 120 has an axial length N of 14 mm., while lower hosel segment 121 has an axial extent P of 12 mm. Distance Q is the horizontal distance from geometric center 146 to the furthest toe extent of the rear portion casting 117, and that value is 50 mm.

The power shaft 113 has an outer diameter of 13 mm. and a wall thickness of 0.8 mm., although shown somewhat heavier in the drawings.

Viewing Fig. 25, face wall 115 has integral reinforcing ribs 152, 153, 154, 155, 156, 157, and 158 extending outwardly from and integral with an annular socket 148. Ribs 152 and 155 extend generally horizontally while ribs 153 and 157 extend generally vertically. Rib 152 connects with and is integral with rib 158 that is integral with and approximately midway up the heel wall 123. As seen in Fig. 24, rib 158 extends all the way to the rear end of the heel wall 123. Rib 153 connects with and is integral with top wall rib 159 that extends centrally in the top wall 117 and rearwardly to the rear end of the top of the power shaft 113 as seen in Fig. 26

Face wall rib 155 connects with and is integral with toe wall rib 161 that extends rearwardly and generally centrally in the toe wall 124 to the rear end of the club

head, as seen in Fig. 26. The top wall has additional ribs 162 and 163 that also extend to the rear end of the top wall 117.

Connecting ribs 162, 163, 164, 165 and 166 interconnect ribs 152 to 157, 157 to 156, 156 to 155, 155 to 154, and 154 to 153 respectively to provide additional reinforcement for face wall 115.

All of these ribs have a width slightly over 3 mm. and a thickness(their extension from the inner surface of the walls from which they project) of about 2 mm.

As seen in Fig. 24, the parting line between the forward portion 111 and the rear portion 112, which are separate castings, is about 21.5 mm. from the lower leading edge of the face wall 115 in a rearward direction along a vertical plane extending along the target line through point 146.

A socket similar to socket 148 can be provided in the rear of the club head to receive the rear end of the power shaft 113 to eliminate welding the power shaft 113 to the rear end of the club. However, minor heat distortion caused by welding the rear end of the club to the rear wall of the club is not a significant problem.

Viewing Figs. 27, 28, 29 and 30, the four clubs in the present line of clubs are depicted with the highest swing speed club depicted in Fig. 27, and the lowest swing speed club depicted in Fig. 30. As may be seen in these Figures, the face wall 115a in the club head 110a seen in Fig. 27 has the heaviest face wall, and hence, the highest face wall modulus of elasticity, the face walls 115b, 115c,

and 115d are progressively thinner with wall 115d having the lowest face wall modulus of elasticity. It should be understood, however, that any number of clubs may constitute a club line according to the present invention, and in fact, in the Fig. 32 Stress Strain Curves, five club heads are illustrated rather than the four shown in Figs. 27 to 30. Ideally, there should be a greater number of clubs in the line to tailor the line to more golfers. If each club head was designed for a 5 mph swing speed range, there could be 15 or more clubs in the line. However, the number of clubs in the line should really not exceed about eight to minimize customer confusion when selecting the swing speed club for his or her range. For explanation purposes only, the club head 110d in Fig. 30 is assumed to be the 50 to 65 mph club head illustrated in Fig. 32; the club head 10c illustrated in Fig. 29 will be assumed to be the 66 to 80 mph illustrated in Fig. 32; the club head 110b depicted in Fig. 28 will be assumed to be the 81 to 95 mph club head in Fig. 32; and the club head 110a depicted in Fig. 27 will be assumed to be the 96 to 105 mph club head in Fig. 32.

The power tube assembly 113 includes an annular tube, welded to an annular socket 171 formed integrally in the rear of the club head, the closure cap 138, the socket 148, and piston 173 welded to the front end of the tube 170 and slidable in socket bore 175.

The piston 173 has a downwardly stepped rear portion 177 that fits inside tube 170, an annular through bore 178, and a central annular groove 179 that receives a rubber "O" ring 181. The outer diameter of the "O" ring 180 is

larger than the outer diameter of the piston 173 to minimize lateral vibration of the piston 173 against the walls of socket bore 183 and reduce the noise level at ball impact. Hole 178 is necessary so that no air is compressed between the forward face of the piston and the socket 175.

The spacing of the piston forward wall 184 from the socket bottom wall 185 is an important aspect of the present invention and is not necessarily, but may be, the same in each of the club heads 110a, 110b, 110c, and 110d. In all of the club heads in the line, however, the swing speed at which the rear of the face wall 115 impacts the forward surface of the piston 184 have a specific relation to the swing speed range for which that club head is designed. For example, the low swing speed range club head 110d; i.e., 50 to 65 mph, might be designed to have a piston impact at 65 mph. It could, however, be somewhat higher or somewhat lower than 65 mph, and the exact impact speed point should best be determined by club head testing. In any event, whatever the relation of piston impact speed to the club head speed range should be consistent with all of the clubs 110a, 110b, 110c, and 110d in the line.

As noted above, the spacing between the forward face 184 of the piston and the bottom wall 185 of the cavity, is shown approximately the same in club head 110a, 110b, 110c, and 110d, but in practice the piston spacing or piston clearance may be different in each of the club heads depending upon the modula of elasticity of face walls 115a, 115b, 115c and 115d.

002120 2074560

Piston clearance is determined experimentally and is selected so that piston impact occurs at about 85% of the strain at the yield point of the face wall. The yield point, of course, is that point on the Stress Strain Curve whereupon relaxation of the face wall it does not follow the Stress Strain Curve during compression. One method for making this determination is with a variety of face wall thicknesses. For example, ten part 11s could be constructed having face wall thicknesses from .050 inches to 0.150 inches in .010 increments. These part 11s are then placed in a compression machine with a plotting stylus, parting line surface downwardly and face wall 115 upwardly. A semi-hemisphere golf ball is then placed between the upper platen and the club face, arcuate surface against the base, of course, and compression testing is conducted using a dial indicator for measuring face deflection from below on the rear of the face wall. The yield point is quite easily determined in a plotting compression testing machine by cycling up and down the stress strain curve with increasing cycle length until the stylus fails to return exactly down the compression line. The maximum deflection at the yield point on the dial indicator is then tabulated for each of the club heads, and since these club heads have reached the yield point, they have been damaged and cannot be used for further testing. Then duplicates of these heads are utilized to make assembled club heads with the clearance space of the piston being 85% of the tabulated yield strains noted in the compression testing. This 15% safety factor is

proportional to the modulus of elasticity of the face wall unsupported by the power piston assembly 113, and the slope of the second portion 189 of the curves represents the modulus of elasticity of the face wall after it impacts the power piston assembly 113 and, of course, in each case is seen to be substantially higher than the slope of portion 187. It should be noted that the slope of the stress strain curves in Fig. 32 is proportional to modulus of elasticity.

As discussed briefly above, the fundamental principles of the present invention can be applied with a lesser benefit to a single club as opposed to a multiple club line. Some manufactures may prefer to utilize these design principles in a single club because they may view the custom clubfitting process as being customer confusing or retailer confusing because it requires measuring the customer's swing speed, usually with an electronic swing speed measuring device. Most average golfers have swing speeds in the range of 60 to 90 mph. If a club manufacturer preferred to make a one club line, the club could be designed so that face wall impact with the front face of the piston would occur at a 90 mph swing speed. This design, of course, would benefit the 85 to 90 mph swing speed the most, with a lesser benefit for those players in the 60 to 85 mph range. And if a player above 90 mph used the club, he would not damage the club because of the increased modulus of elasticity above 90 mph. This benefit is also characteristic of the multiple club line designs described above when using swing speeds above each of the designed ranges.

1 CLAIMS

2 1. A golf club, comprising: a club head, and a
3 shaft connected to the club head, said club head including a
4 body having a ball striking face wall and a perimeter wall
5 extending rearwardly from the face wall, and an abutment
6 fixed in the club head body spaced rearwardly from the ball
7 striking face wall positioned sufficiently close to the face
8 wall so the face wall impacts the abutment at a given club
9 head speed, said abutment including a generally planar wall
10 fixed in the club head body extending behind and across a
11 substantial portion of the ball striking face wall.
12

13 2. A golf club as defined in Claim 1, wherein the
14 face wall is thinner than .100 inches, and the generally
15 planar wall has reinforcing elements on its rear surface.
16

17 3. A golf club as defined in Claim 1, wherein the
18 generally planar wall is substantially parallel to and ex-
19 tends across the ball striking face wall.
20

21 4. A line of golf clubs designed to customize the
22 golf club to the swing speed range of the golfer, compris-
23 ing: a plurality of golf clubs each including a club head
24 with a shaft connected thereto, each of the club heads in-
25 cluding a body with a ball striking face wall and a
26 perimeter wall extending rearwardly from the ball striking
27 face wall, a generally planar secondary wall in the club
28 head body, generally parallel to and extending a substantial
29 distance across and behind the ball striking face wall, the
30 ball striking face wall in at least one of the golf clubs

having a higher modulus of elasticity than the ball striking face wall in at least another of the golf clubs, said secondary wall being spaced sufficiently close to the ball striking face wall so the face wall impacts the secondary wall at a given club head speed.

5. A line of golf clubs as defined in Claim 4, wherein the ball striking face wall in at least one of the golf clubs is generally thinner than the ball striking face wall in another of the golf clubs.

6. A line of golf clubs as defined in Claim 4, wherein the secondary wall is spaced further from the ball striking face wall in at least one of the golf clubs than the secondary wall is spaced from the ball striking face wall in at least another of the golf clubs.

7. A line of golf clubs as defined in Claim 4, wherein the club head body has a standardized configuration, said face wall including a plurality of different modulus face walls interchangeable in the standardized club head body.

8. A line of golf clubs as defined in Claim 4, wherein the face walls have different thickness to vary the face modulus in each.

1 9. A line of golf clubs as defined in Claim 4,
2 wherein the higher modulus face wall club head has a second-
3 dary wall spaced closer to the face wall than the lower
4 modulus face wall club head secondary wall.

5
6 10. A line of golf clubs, comprising: a
7 plurality of golf clubs each including a club head body
8 having a shaft connected thereto, said club head body being
9 standardized within the line and including a perimeter wall
10 and a face wall receiving element, and a plurality of dif-
11 ferent modulus of elasticity face walls fixed to the body
12 face wall receiving element.

13
14 11. A line of golf clubs as defined in Claim 10,
15 wherein the face walls have a progressively increasing
16 thickness in the line.

17
18 12. A line of golf clubs as defined in Claim 10,
19 wherein the club head body has an abutment wall spaced from
20 and immediately behind the face wall, said abutment wall
21 being sufficiently close to the face wall so the face wall
22 impacts the abutment wall at a given swing speed.

23
24 13. A golf club head, comprising: a club head
25 body having a ball striking face wall and a perimeter wall
26 extending generally rearwardly from at least a portion of
27 the ball striking face wall, said face wall being relatively
28 thin to enhance face deflection at the club head speeds for
29 which the club head is designed, and means for minimizing
30

1 the ball striking face wall from exceeding its elastic limit
2 including a generally planar wall closely spaced behind the
3 ball striking face wall.

4
5 14. A golf club head, comprising: a head body
6 having a ball striking face wall and a perimeter wall ex-
7 tending generally rearwardly from at least a portion of the
8 ball striking face wall, said face wall being the thinnest
9 possible without exceeding about 80% of the elastic limit
10 for the upper club head speed for which the club head is
11 designed, and a secondary planar wall in the club head
12 separate from the face wall for permitting free flexure of
13 face wall in a lower speed range and for limiting face wall
14 deflection to minimize face wall exceeding its elastic limit
15 in an upper speed range.

16
17 15. A golf club head designed to augment ball
18 exit velocity, comprising: a club head body having a face
19 wall, a generally rearwardly extending perimeter wall about
20 at least a portion of the face wall, the face wall being
21 relatively thin to maximize face deflection and face energy
22 applied to the ball without exceeding the elastic limit of
23 the face, said face thickness being selected so the face has
24 a first lower modulus of elasticity in a lower swing speed
25 range, and a secondary planar wall in the club head body for
26 providing the face wall with a higher modulus of elasticity
27 in a second higher swing speed range.

16. A golf club head as defined in Claim 15, wherein the second higher modulus of elasticity occurs at about 80% of the elastic limit of the face wall.

17. A golf club head as defined in Claim 15, said secondary planar wall in the club head body for providing the face wall with a second higher modulus of elasticity in a higher speed range limits movement of the face wall rearwardly along the target line during impact with a ball.

18. A golf club head as defined in Claim 17, wherein said secondary wall is spaced from the face wall to retard movement of the face wall after a deflection that approaches the elastic limit of the face wall, said spacing being selected so that when the face wall strikes the secondary wall, the face wall is about at least 80% of its elastic limit.

19. A golf club head as defined in Claim 15, wherein the secondary wall in the club head for providing the face wall with a second higher modulus of elasticity in a speed range extends substantially across the face wall and has a plurality of reinforcing ribs thereon.

20. A line of golf clubs production customized for golfers' swing speeds, comprising: a plurality of golf club heads having similar shapes and weights, a plurality of shafts connected to the club heads, each of said club heads having a ball striking face wall and a perimeter wall that extends rearwardly from at least a portion of the face wall,

002720 2044560

1 said line of clubs being constructed so that modulus of
2 elasticity of the face walls in each of a plurality of dis-
3 crete swing speed ranges increases as the swing speed ranges
4 increase, said face modulus of elasticity being low in a
5 lower portion of each of the speed ranges to provide in-
6 creased face wall deflection near the elastic limit of the
7 face wall in each swing speed range, and a secondary planar
8 wall to increase the modulus of elasticity in each club in
9 the line in an upper portion of each of the swing speed
10 ranges.

OATH

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name; that

I believe I am the original, first and sole inventor(if only one name is listed below), or an original, first and joint inventor(if plural names are listed below) of the improvement in the IMPROVED GOLF CLUB FACE FLEXURE CONTROL SYSTEM, Case G33, described and claimed in the foregoing specification; that this application in part discloses and claims subject matter disclosed in my earlier filed application, United States Serial No. 09/344,172, Filed: June 24, 1999, entitled GOLF CLUB FACE FLEXURE CONTROL SYSTEM; that I acknowledge my duty to disclose information of which I am aware which is material to the examination of this application;

I hereby state that I have reviewed and understand the contents of the above-identified specification, including the claims of this specification, and that as to the subject matter of this application which is common to said earlier application, I do not know and do not believe that the same was ever known or used in the United States of America before my invention thereof or patented or described in any printed publication in any country before my invention thereof or more than one year prior to said earlier application, or in public use or on sale in the United States of America more than one year prior to said earlier application; that said common subject has not been patented or made the subject of an inventor's certificate issued before the date of said earlier application in any country foreign to the United States of America on an application filed by me or my legal representatives or assigns more than twelve (12) months prior to said earlier application; and that no application for patent or inventor's certificate on said invention has been filed by me or my representatives or assigns in any country foreign to the United States of America, except as follows: NONE.

That as to the subject matter of this application which is not common to said earlier application, I do not know and do not believe that the same was ever known or used in the United States of America before my invention thereof or patented or described in any printed publication in any country before my invention thereof or more than one year prior to the date of this application, or in public use or on sale in the United States of America more than one year prior to the date of this application, and that said subject matter has not been patented or made the subject of an inventor's certificate issued in any country foreign to the United States of America on an application filed by me or my legal representatives or assigns more than twelve months prior to the date of this application; and

09544107 071200

That no application for patent or inventor's certificate in said invention has been filed by me or my representatives or assigns in any country foreign to the United States of America except as follows: None.

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued.

I hereby appoint DILLIS V. ALLEN, Esq., Registration No. 22,460, 1080 Nerge Road, Suite 205, Elk Grove Village, Illinois 60007, my attorney, with full power of substitution and revocation, to prosecute this application, to make alterations and amendments therein, to receive the patent, and to transact all business in the Patent and Trademark Office connected therewith.

All official correspondence should be forwarded to Dillis V. Allen, Esq., 1080 Nerge Road, Suite 205, Elk Grove Village, Illinois 60007; Telephone No. 847/895-9100.

Full name of sole or first inventor: Dillis V. Allen

Inventor's signature [Signature] Date July 6, 2000

Residence: 31W211 Route 58, Elgin, Illinois 60120

Citizenship: United States

Post Office Address: 31W211 Route 58, Elgin, Illinois 60120

Full name of second inventor:

Inventor's signature _____ Date _____

Residence:

Citizenship:

Post Office Address:

STATE OF ILLINOIS)
COUNTY OF COOK)

Personally came before me this 6th day of July, 2000, the above-named Dillis V. Allen, to me known to be the same person who executed the foregoing instrument and acknowledged the same.

[Signature]
Notary Public
My commission expires 10-18-01.
